# Applications

If  $J$  is a perturbation of  $J_0 \in \mathcal{T}_\epsilon$ ,  $\Delta(J)$  will be a perturbation of  $S^n + S^{-n}$ .  $\Delta(J)$  will have only  $n$  non-zero diagonals above and below the main. That means by using  $n \times n$  blocks, it will be tridiagonal. It is what is called a block Jacobi matrix. Notice that  $S^n + S^{-n}$  has 0 diagonal blocks and  $\mathbb{1}$  off-diagonal blocks.

For example, it is easy to extend Lieb-Thirring bounds on eigenvalues outside  $[-2, 2]$  to the block case and this leads one to proofs of Lieb-Thirring bounds on eigenvalues outside  $\epsilon$  for perturbations of  $J_0 \in \mathcal{T}_\epsilon$ .

# Applications

If  $J$  is a perturbation of  $J_0 \in \mathcal{T}_\epsilon$ ,  $\Delta(J)$  will be a perturbation of  $S^n + S^{-n}$ .  $\Delta(J)$  will have only  $n$  non-zero diagonals above and below the main. That means by using  $n \times n$  blocks, it will be tridiagonal. It is what is called a block Jacobi matrix. Notice that  $S^n + S^{-n}$  has 0 diagonal blocks and  $\mathbb{1}$  off-diagonal blocks.

For example, it is easy to extend Lieb-Thirring bounds on eigenvalues outside  $[-2, 2]$  to the block case and this leads one to proofs of Lieb-Thirring bounds on eigenvalues outside  $\epsilon$  for perturbations of  $J_0 \in \mathcal{T}_\epsilon$ .

It is easy to get a Killip-Simon theorem on the equivalence of  $\Delta(J) - S^n - S^{-n}$  in Hilbert Schmidt class. The hard work in the DKS result is translate that into information about  $J$  and that was only possible if all gaps were open.

The key is to find an orthonormal basis in which  $J$  and  $(J - c_j)^{-1}$ ,  $j = 1, \dots, \ell$  are all of width  $2\ell + 1$ .

This issue has been addressed in related but distinct contexts, perhaps most famously for the CMV matrix. In that case, for general OPUC, multiplication by  $z$ , denote it by  $U$  in the OPUC basis has only one diagonal below but generally infinitely many diagonals above.

If  $J \in \mathcal{T}_\epsilon$  and  $\Delta$  is the Yuditskii discriminant of  $\epsilon$ , then  $\Delta(J)$  clearly has spectrum  $[-2, 2]$  with multiplicity  $N \equiv \ell + 1$  and it can be shown to be purely a.c. so it is unitarily equivalent to  $S^N + S^{-N}$ . But since  $(J - c_j)^{-1}$  is not finite width, they cannot be equal. The key is to find an orthonormal basis in which  $J$  and  $(J - c_j)^{-1}$ ,  $j = 1, \dots, \ell$  are all of width  $2\ell + 1$ .

This issue has been addressed in related but distinct contexts, perhaps most famously for the CMV matrix. In that case, for general OPUC, multiplication by  $z$ , denote it by  $U$  in the OPUC basis has only one diagonal below but generally infinitely many diagonals above. But, if instead, one orthonormalizes  $\{1, z, z^{-1}, z^2, z^{-2}, \dots\}$ , both  $U$  and  $U^{-1} = U^*$  have only two non-zero diagonals below,

# Functional Model for Isospectral Torus

For this last topic, let's shift to an additive view of  $\Gamma^*$  and use  $\mu$  for the character of  $B \equiv B_0$ . Now let  $\mathcal{H}_\alpha$  be the set of elements in  $H^2$  which are character automorphic with character  $\alpha$ . Since  $f \mapsto f(0)$  is continuous on  $\mathcal{H}_\alpha$ , there exists  $k_\alpha \in \mathcal{H}_\alpha$  so that  $\langle k_\alpha, f \rangle = f(0)$ . (More generally there is a full reproducing kernel which is useful in further developments.)

Isospectral Torus

# Functional Model for Isospectral Torus

For this last topic, let's shift to an additive view of  $\Gamma^*$  and use  $\mu$  for the character of  $B \equiv B_0$ . Now let  $\mathcal{H}_\alpha$  be the set of elements in  $H^2$  which are character automorphic with character  $\alpha$ . Since  $f \mapsto f(0)$  is continuous on  $\mathcal{H}_\alpha$ , there exists  $k_\alpha \in \mathcal{H}_\alpha$  so that  $\langle k_\alpha, f \rangle = f(0)$ . (More generally there is a full reproducing kernel which is useful in further developments.) Thus  $\|k_\alpha\|^2 = k_\alpha(0)$  so  $\widetilde{k}_\alpha(z) = k_\alpha(0)^{-1/2}k_\alpha(z)$  is a unit vector.

Notice that  $\{f \in \mathcal{H}_\alpha | f(0) = 0\}^\perp$  includes  $\widetilde{k}_\alpha$ . Also notice, that if  $f$  is in the set whose orthogonal complement we just wrote, then  $B^{-1}f$  lies in  $\mathcal{H}_{\alpha-\mu}$  so  $\mathcal{H}_\alpha = [\widetilde{k}_\alpha] \oplus B\mathcal{H}_{\alpha-\mu}$ .

Therefore if we define  $e_n^\alpha \equiv B^n \widetilde{k}_{\alpha-n\mu}$ , we see that  $\{e_n^\alpha\}_{n=0}^\infty$  is an orthonormal basis for  $\mathcal{H}_\alpha$ .
